

**PRODUCT NAME**

INVEGA® Extended-Release Tablets

International Non-Proprietary Name

Paliperidone

DOSAGE FORMS AND STRENGTHS

INVEGA® contains 3, 6, 9 mg of paliperidone.

The chemical name is (±)-3-[2-[4-(6-fluoro-1,2-benzisoxazol-3-yl)-1-piperidinyl]ethyl]-6,7,8,9-tetrahydro-9-hydroxy-2-methyl-4H-pyrido[1,2-a]pyrimidin-4-one.

For excipients, see List of excipient.

PHARMACODYNAMIC PROPERTIES**Pharmacodynamic Properties**

Pharmacotherapeutic group: Antipsychotics, other antipsychotics, ATC code: N05AX13.

Mechanism of Action

Paliperidone, the active ingredient in INVEGA®, is a psychotropic agent belonging to the chemical class of benzisoxazole derivatives (atypical neuroleptic antipsychotic). INVEGA® contains a racemic mixture of (+)- and (-)-paliperidone.

Paliperidone is a centrally active dopamine D₂ antagonist with predominant serotonergic 5-HT_{2A} antagonistic activity. Paliperidone is also active as an antagonist at α_1 and α_2 adrenergic receptors and H₁ histaminergic receptors. Paliperidone has no affinity for cholinergic muscarinic or β_1 - and β_2 -adrenergic receptors. The pharmacological activity of the (+)- and (-)- paliperidone enantiomers is qualitatively and quantitatively similar.

The mechanism of action of paliperidone, as with other drugs having efficacy in schizophrenia, is unknown. However, it has been proposed that the drug's therapeutic activity in schizophrenia is mediated through a combination of dopamine Type 2 (D₂) and serotonin Type 2 (5HT_{2A}) receptor antagonism. Antagonism at receptors other than D₂ and 5HT_{2A} may explain some of the other effects of paliperidone.

Polysonnography

Centrally-acting medications through their mechanism of action, drug-release profile, and/or time of dose administration may affect sleep. To evaluate the impact of morning dosing of INVEGA® on sleep architecture and continuity, a placebo-controlled study was conducted in 36 subjects with schizophrenia in which INVEGA 9 mg or placebo was administered once daily for 14 days. The following observations were made (mean data compared with placebo): reduced latency to persistent sleep by 41.0 (SE 18.70) minutes, decreased sleep onset latency by 35.2 (SE 14.99) minutes, decreased number of awakenings after sleep onset by 7.0 (SE 3.88) events, increased total sleep time by 52.8 (SE 24.01) minutes, increased sleep period time by 41.7 (SE 18.75) minutes, and increased sleep efficiency index by 11.0% (SE 5.00). There was also a statistically significant decrease (relative to placebo) in Stage 1 sleep of 11.9 (SE 4.44) minutes and increase in Stage 2 sleep of 50.7 (SE 17.67) minutes. No clinically relevant effect on REM sleep was observed.

Clinical Efficacy**Schizophrenia - adults**

The efficacy of INVEGA® was established in three placebo-controlled, double-blind, 6-week trials in subjects who met DSM-IV criteria for schizophrenia. An active control (olanzapine) was included for assay sensitivity

purposes. INVEGA® doses, which varied across the three studies, ranged from 3 to 15 mg once daily. Efficacy was evaluated using the Positive and Negative Syndrome Scale (PANSS); the primary endpoint was decrease in total PANSS scores. An examination of population subgroups did not reveal any evidence of differential responsiveness on the basis of age, race, or gender. Secondary endpoints were also assessed, including Personal and Social Performance (PSP) and the Clinical Global Impression - Severity (CGI-S) scale. The PSP is a validated clinician-rated scale that measures four areas of personal and social functioning (socially useful activities including work and study, personal and social relationships, self-care, and disturbing and aggressive behaviors). The CGI-S is an independent investigator-rated assessment of overall severity of illness. In a pooled analysis of these three studies, each dose of INVEGA® was superior to placebo on the PSP and CGI-S. In addition, the effect on PSP was distinct from the improvement in symptoms as measured by the primary endpoint, total PANSS. Further evaluation of the open-label extensions of these three studies showed that flexibly-dosed INVEGA® (3 to 15 mg once daily) for up to 52 weeks was associated with continued improvement on PSP.

In a long-term trial designed to assess the maintenance of effect, INVEGA® was significantly more effective than placebo in maintaining symptom control and delaying recurrence of schizophrenia. In this study, adults who met DSM-IV criteria for schizophrenia and who remained clinically stable on an established dose of INVEGA® during an 8-week period of open-label treatment (doses ranging from 3 to 15 mg once daily) after having been treated for an acute episode for the previous 6 weeks with INVEGA® (doses ranging from 3 to 15 mg once daily) were then randomized in a double-blind manner to either continue on INVEGA® at their achieved stable dose or to placebo until they experienced a recurrence of schizophrenia symptoms. The trial was stopped early for efficacy reasons based on an interim analysis that achieved predefined criteria by showing a significantly longer time to recurrence in patients treated with INVEGA® compared to placebo ($p=0.0053$). Based on final analysis (including also those patients included after the cut-off point for the interim analysis), the rate of recurrence events was 22.1% in the INVEGA® group compared with 51.5% in the placebo group. A significant improvement in symptoms was achieved at the end of the open-label stabilization phase (decrease in PANSS total scores of 38 [SD ± 16.03] points), but after randomization to double-blind treatment, the patients receiving placebo deteriorated significantly more than those on INVEGA® ($p<0.001$). INVEGA® was also significantly more effective than placebo in maintaining personal and social performance. During the double-blind phase of this study as measured by the CGI-S scale, there was worsening on the overall severity of psychosis in the placebo group, while patients treated with INVEGA® remained clinically stable.

Bipolar Disorder

The efficacy of INVEGA® in the treatment of acute manic episodes was established in two multicenter, placebo-controlled, double-blind trials in subjects who met DSM-IV criteria for Bipolar I Disorder, most recent episode manic or mixed. One study evaluated the efficacy and safety of INVEGA® over a flexible dose range of 3-12 mg relative to placebo and quetiapine over a 12-week period, while the other study evaluated the efficacy and safety of fixed doses of INVEGA® (3 mg, 6 mg, and 12 mg) relative to placebo over a 3-week period. INVEGA® over a flexible dose range of 3 to 12 mg and at a fixed dose of 12 mg was superior to placebo with regard to the primary efficacy variable, change in YMRS total score from baseline at the 3-week endpoint. Superiority to placebo was established as early as Day 2, and antimanic efficacy compared to placebo was maintained at every subsequent assessment for up to 3 weeks. After 3 weeks of treatment, over one-half of subjects treated with INVEGA® were rated as treatment responders. Flexibly dosed INVEGA® was statistically superior to placebo with regard to both the rate of response and remission at Week 3. The efficacy observed for the primary efficacy variable was supported by improvements in secondary efficacy variables such as global measures of disease severity (CGI-BP-S) and function (GAF), as well as psychotic symptoms (PANSS).

Over the 12-week double-blind treatment period of the flexible-dose study, INVEGA® was shown noninferior to quetiapine in the authorized dose range for the primary efficacy variable using a predefined noninferiority margin. In a separate multicenter, placebo-controlled, double-blind trial in subjects with Bipolar I Disorder, most recent episode manic or mixed, INVEGA® was shown to be well tolerated when used in combination with the mood stabilizers, lithium or valproate, over a period of 6 weeks, while the incremental benefit of INVEGA® as adjunctive therapy was not demonstrated in this study.

Schizoaffective Disorder

The efficacy of INVEGA® (3 mg to 12 mg once daily) in the treatment of schizoaffective disorder was established in two placebo-controlled, 6-week trials in non-elderly adult subjects who met DSM-IV criteria for schizoaffective disorder, as confirmed by the Structured Clinical Interview for DSM-IV Disorders. In one of these trials, efficacy was assessed in 203 subjects who were assigned to one of two dose levels of INVEGA®: 6 mg with the option to reduce to 3 mg (n = 105) or 12 mg with the option to reduce to 9 mg (n = 98) once daily. In the other study, efficacy was assessed in 211 subjects who received flexible doses of INVEGA® (3-12 mg once daily). Both studies included subjects who received INVEGA® either as monotherapy [no mood stabilizers and/or antidepressants (55%)] or as an adjunct to mood stabilizers and/or antidepressants (45%). The most commonly used mood stabilizers were valproate and lithium. The most commonly used antidepressants were SSRIs and SNRIs. INVEGA® was dosed in the morning without regard to meals. Studies were carried out in the United States, Eastern Europe, Russia, and Asia.

Efficacy was evaluated using the Positive and Negative Syndrome Scale (PANSS), a validated multi-item inventory composed of five factors to evaluate positive symptoms, negative symptoms, disorganized thoughts, uncontrolled hostility/excitement, and anxiety/depression.

As secondary outcomes, mood symptoms were evaluated using the Hamilton Depression Rating Scale (HAM-D-21) and the Young Mania Rating Scale (YMRS).

The higher dose group of INVEGA® in the 2 dose-level study (12 mg/day with option to reduce to 9 mg/day), and the INVEGA® group in the flexible-dose study (dosed between 3 and 12 mg/day, mean modal dose of 8.6 mg/day) were each superior to placebo in the PANSS. In the lower dose group of the 2 dose-level study (6 mg/day with option to reduce to 3 mg/day), INVEGA® was not significantly different from placebo as measured by the PANSS.

Numerical improvements in mood symptoms were also observed, as measured by the HAM-D 21 and YMRS.

Taking the results of both studies together, INVEGA® improved the symptoms of schizoaffective disorder at endpoint relative to placebo when administered either as monotherapy or in combination with antidepressants and/or mood stabilizers. An examination of population subgroups did not reveal any evidence of differential responsiveness on the basis of gender, age, or geographic region. There were insufficient data to explore differential effects based on race.

Pharmacokinetic Properties

The pharmacokinetics of paliperidone following INVEGA® administration are dose-proportional within the recommended clinical dose range (3 to 12 mg).

Absorption

Following a single dose of INVEGA®, the plasma concentrations of paliperidone steadily rise to reach peak plasma concentration (C_{max}) in approximately 24 hours after dosing. With once-daily dosing of INVEGA®, steady-state concentrations of paliperidone are attained within 4-5 days of dosing in most subjects.

The release characteristics of INVEGA® result in minimal peak-trough fluctuations as compared to those observed with immediate-release risperidone. In a study comparing the steady-state pharmacokinetics following once-daily administration of 12 mg paliperidone (administered as extended-release tablets) with 4 mg immediate-release risperidone in schizophrenic subjects, the fluctuation indexes were 38% for paliperidone extended-release compared to 125% for risperidone immediate-release (see Figure 1).

Figure 1. Steady-state concentration profile following administration of 12 mg paliperidone administered as six 2 mg extended-release [prolonged-release] tablets once daily for 6 days (paliperidone concentrations are represented) compared with risperidone immediate-release administered as 2 mg once daily on Day 1 and 4 mg once daily on Days 2 to 6 (paliperidone+risperidone concentrations are represented).

Following administration of INVEGA®, the (+) and (-) enantiomers of paliperidone interconvert, reaching an AUC (+) to (-) ratio of approximately 1.6 at steady state. The absolute oral bioavailability of paliperidone following INVEGA® administration is 28%.

Following administration of a single 15 mg paliperidone extended-release [prolonged-release] tablet to healthy subjects, confined to bed for 36 hours, with a standard high-fat/high-caloric meal, the C_{max} and AUC values increased by 42% and 46%, respectively, compared with administration under fasting conditions. In another study involving healthy ambulatory subjects, the C_{max} and AUC of paliperidone following administration of a single 12 mg paliperidone prolonged-release tablet with a standard high-fat/high-caloric meal resulted in increases of 60% and 54%, respectively, compared with administration under fasting conditions. Although the presence or absence of food at the time of INVEGA® administration may increase or decrease exposure to paliperidone, these changes are not considered clinically relevant. Clinical trials establishing the safety and efficacy of INVEGA® were carried out in subjects without regard to the timing of meals. (See Section *Dosage and Administration*).

In the Phase 3 studies of INVEGA® tablets in Bipolar I Disorder, median dose normalized paliperidone plasma concentrations at 8 hours postdose after 6 days of treatment were comparable between fasted subjects and subjects who had consumed a standard continental or high-caloric breakfast between 2 hours before and 1 hour after their medication intake.

Distribution

Paliperidone is rapidly distributed. The apparent volume of distribution is 487 L. The plasma protein binding of paliperidone is 74%. It binds primarily to α_1 -acid glycoprotein and albumin. *In vitro*, high therapeutic concentrations of diazepam (3 mcg/mL), sulfamethazine (100 mcg/mL), warfarin (10 mcg/mL), and carbamazepine (10 mcg/mL) caused a slight increase in the free fraction of paliperidone at 50 ng/mL. These changes are not expected to be of clinical significance.

Metabolism and Elimination

One week following administration of a single oral dose of 1 mg immediate-release ^{14}C -paliperidone, 59% of the dose was excreted unchanged into urine, indicating that paliperidone is not extensively metabolized in the liver. Approximately 80% of the administered radioactivity was recovered in urine and 11% in the feces.

Four metabolic pathways have been identified *in vivo*, none of which accounted for more than 6.5% of the dose: dealkylation, hydroxylation, dehydrogenation, and benzisoxazole scission. Although *in vitro* studies suggested a role for CYP2D6 and CYP3A4 in the metabolism of paliperidone, there is no evidence *in vivo* that these isozymes play a significant role in the metabolism of paliperidone. Despite the large variation in the general population with regard to the ability to metabolize CYP2D6 substrates, population pharmacokinetics analyses indicated no discernable difference on the apparent clearance of paliperidone after administration of INVEGA® between extensive metabolizers and poor metabolizers of CYP2D6 substrates. *In vitro* studies using microsomal preparations of heterologous systems indicate that CYP1A2, CYP2A6, CYP2C9, CYP2C19, and CYP3A5 are not involved in the metabolism of paliperidone. The terminal elimination half-life of paliperidone is about 23 hours.

Special Populations

Elderly

Data from a pharmacokinetic study in elderly subjects (≥ 65 years of age, $n = 26$) indicated that the apparent steady-state clearance of paliperidone following INVEGA® administration was 20% lower compared to that of adult subjects (18-45 years of age, $n = 28$). However, there was no discernable effect of age in the population pharmacokinetic analysis involving schizophrenia subjects after correction of age-related decreases in CrCl.

Renal Impairment

The dose should be reduced in patients with moderate and severe renal impairment (see *Dosage and Administration*). The disposition of paliperidone was studied in subjects with varying degrees of renal function. Elimination of paliperidone decreased with decreasing creatinine clearance (CrCl). Total clearance of paliperidone was reduced in subjects with impaired renal function by 32% in mild (CrCl = 50 to < 80 mL/min), 64% in moderate (CrCl = 30 to < 50 mL/min), and 71% in severe (CrCl = 10 to < 30 mL/min) renal impairment. The mean terminal elimination half-life of paliperidone was 24, 40, and 51 hours in subjects with mild, moderate, and severe renal impairment, respectively, compared with 23 hours in subjects with normal renal function (CrCl ≥ 80 mL/min).

Hepatic Impairment

Paliperidone is not extensively metabolized in the liver. In a study in subjects with moderate hepatic impairment (Child-Pugh class B), the plasma concentrations of free paliperidone were similar to those of healthy subjects. Paliperidone has not been studied in patients with severe hepatic impairment.

Race

No dosage adjustment is recommended based on race. Population pharmacokinetics analysis revealed no evidence of race-related differences in the pharmacokinetics of paliperidone following INVEGA® administration. No differences in pharmacokinetics were observed in a pharmacokinetics study conducted in Japanese and Caucasian subjects.

Gender

The apparent clearance of paliperidone following INVEGA® administration is approximately 19% lower in women than men. This difference is largely explained by differences in lean body mass and creatinine clearance between men and women, as a population pharmacokinetics evaluation revealed no evidence of clinically significant gender-related differences in the pharmacokinetics of paliperidone following INVEGA® administration after correction for lean body mass and creatinine clearance.

Smoking Status

Based on *in vitro* studies utilizing human liver enzymes, paliperidone is not a substrate for CYP1A2; smoking should, therefore, not have an effect on the pharmacokinetics of paliperidone. Consistent with these *in vitro* results, population pharmacokinetic evaluation has not revealed any differences between smokers and non-smokers.

NON-CLINICAL INFORMATION

Toxicology

As with other drugs that antagonize dopamine D₂ receptors, paliperidone elevated serum prolactin levels in repeat-dose toxicity studies.

Carcinogenicity

The carcinogenic potential of paliperidone, an active metabolite of risperidone, was assessed based on studies with risperidone conducted in mice and rats. Risperidone was administered at doses up to 10 mg/kg/day for 18 months to mice and for 25 months to rats. There were statistically significant increases in pituitary gland adenomas, endocrine pancreas adenomas, and mammary gland adenocarcinomas. An increase in mammary, pituitary, and endocrine pancreas tumors has been found in rodents after chronic administration of other antipsychotic drugs and is considered to be mediated by prolonged dopamine D₂ antagonism. The relevance of these tumor findings in rodents in terms of human risk is unknown.

Mutagenicity

No evidence of mutagenic potential for paliperidone was found in the Ames reverse mutation test, the mouse lymphoma assay, or the rat micronucleus test.

Impairment of Fertility

Although paliperidone treatment resulted in prolactin- and CNS-mediated effects, the fertility of male and female rats was not affected. At a maternally toxic dose, female rats showed a slightly lower number of live embryos.

CLINICAL INFORMATION

Indications

- INVEGA® is indicated for the treatment of schizophrenia.
- Acute manic and mixed episodes associated with bipolar disorder.
- Schizoaffective disorder as monotherapy and in combination with antidepressants and/or mood stabilizers.

Dosage and Administration

Adults (≥ 18 Years of Age)

INVEGA® is for oral administration and can be administered with or without food.

INVEGA® must be swallowed whole with the aid of liquids, and must not be chewed, divided, or crushed. The medication is contained within a non-absorbable shell designed to release the drug at a controlled rate. The tablet shell, along with insoluble core components, is eliminated from the body; patients should not be concerned if they occasionally notice in their stool something that looks like a tablet.

Schizophrenia

The recommended dose of INVEGA® for the treatment of schizophrenia is 6 mg once daily, administered in the morning. Initial dose titration is not required. Some patients may benefit from lower or higher doses within the recommended range of 3 to 12 mg once daily. Dosage adjustment, if indicated, should occur only after clinical reassessment. When dose increases are indicated, increments of 3 mg/day are recommended and generally should occur at intervals of more than 5 days.

Bipolar Disorder

The recommended dose of INVEGA® for the treatment of acute manic and mixed episodes associated with bipolar I disorder is 9 mg once daily, administered in the morning. Initial dose titration is not required. Some patients may benefit from lower or higher doses within the recommended range of 3 to 12 mg once daily. Dosage adjustment, if indicated, should occur only after clinical reassessment. A dose increase to 12 mg/day, if indicated, should occur at an interval of 2 days or more.

Schizoaffective Disorder

The recommended dose of INVEGA® for the treatment of schizoaffective disorder is 6 mg once daily, administered in the morning. Initial dose titration is not required. Some patients may benefit from lower or higher doses within the recommended dose range of 3 to 12 mg once daily. A general trend for greater effects

was seen with higher doses. This trend must be weighed against dose-related increase in adverse reactions. Dosage adjustment, if indicated, should occur only after clinical reassessment. When dose increases are indicated, increments of 3 mg/day are recommended and generally should occur at intervals of more than 4 days.

The maximum recommended dose is 12 mg/day.

Patients with Hepatic Impairment

No dose adjustment is required in patients with mild or moderate hepatic impairment. As INVEGA® has not been studied in patients with severe hepatic impairment, caution is recommended in such patients.

Patients with Renal Impairment

Dosing must be individualized according to the patient's renal function status. For patients with mild renal impairment (creatinine clearance ≥ 50 mL/min to < 80 mL/min), the recommended initial dose of INVEGA® is 3 mg once daily. The dose may then be increased to a maximum of 6 mg once daily based on clinical response and tolerability. For patients with moderate to severe renal impairment (creatinine clearance ≥ 10 mL/min to < 50 mL/min), the recommended initial dose of INVEGA® is 1.5 mg once daily, which may be increased to a maximum of 3 mg once daily after clinical reassessment. As INVEGA® has not been studied in patients with creatinine clearance below 10 mL/min, use is not recommended in such patients.

Elderly

Dosing recommendations for elderly patients with normal renal function (≥ 80 mL/min) are the same as for adults with normal renal function (see first paragraph in *Dosage and Administration*). However, because elderly patients may have diminished renal function, dose adjustments may be required according to their renal function status (see Section Patients with Renal Impairment above).

Adolescents and Children

Safety and effectiveness of INVEGA® in patients < 18 years of age have not been studied.

Other Special Populations

No dose adjustment for INVEGA® is recommended based on gender, race, or smoking status. (For pregnant women and nursing mothers, see Section *Pregnancy and Breast-feeding*)

Switching to other antipsychotic medicinal products

There are no systematically collected data to specifically address switching patients from INVEGA to other antipsychotic agents. Due to different pharmacodynamic and pharmacokinetic profiles among antipsychotic products, supervision by a clinician is needed when switching to another antipsychotic product is considered medically appropriate.

CONTRAINDICATIONS

INVEGA is contraindicated in patients with a known hypersensitivity to paliperidone or to any of the components in the formulation. Since paliperidone is an active metabolite of risperidone, INVEGA® is contraindicated in patients with a known hypersensitivity to risperidone.

WARNINGS AND PRECAUTIONS

Neuroleptic Malignant Syndrome

Neuroleptic Malignant Syndrome (NMS), characterized by hyperthermia, muscle rigidity, autonomic instability, altered consciousness, and elevated serum creatinine phosphokinase levels has been reported to occur with antipsychotic drugs, including paliperidone. Additional clinical signs may include myoglobinuria (rhabdomyolysis) and acute renal failure. If a patient develops signs or symptoms indicative of NMS, all antipsychotic drugs, including INVEGA®, should be discontinued.

Tardive Dyskinesia/extrapyramidal symptoms

Drugs with dopamine receptor antagonistic properties have been associated with the induction of tardive dyskinesia characterized by rhythmical, involuntary movements, predominantly of the tongue and/or face. If signs and symptoms of tardive dyskinesia appear, the discontinuation of all antipsychotic drugs, including INVEGA®, should be considered.

Extrapyramidal symptoms and psychostimulants

Caution is warranted in patients receiving both psychostimulants (e.g. methylphenidate) and paliperidone concomitantly, as extrapyramidal symptoms could emerge when adjusting one or both medications. Gradual withdrawal of one or both treatments should be considered (see Section *Interactions*).

QT interval

As with other antipsychotics, caution should be exercised when INVEGA® is prescribed in patients with a history of cardiac arrhythmias, in patients with congenital long QT syndrome, and in concomitant use with drugs known to prolong the QT interval. (see Pharmacodynamic Properties: Effect on QT/QTc interval and cardiac physiology).

Hyperglycemia and Diabetes Mellitus

Hyperglycemia, diabetes mellitus, and exacerbation of pre-existing diabetes have been reported during treatment with INVEGA®. Assessment of the relationship between atypical antipsychotic use and glucose abnormalities is complicated by the possibility of an increased background risk of diabetes mellitus in patients with schizophrenia and the increasing incidence of diabetes mellitus in the general population. Given these confounders, the relationship between atypical antipsychotic use and hyperglycemia-related adverse events is not completely understood. Any patient treated with atypical antipsychotics, including INVEGA®, should be monitored for symptoms of hyperglycemia and diabetes mellitus. (See Section *Adverse Reactions*).

Weight Gain

Weight gain has been observed with atypical antipsychotic use. Clinical monitoring of weight is recommended.

Orthostatic Hypotension

Paliperidone may induce orthostatic hypotension in some patients based on its alpha-blocking activity. INVEGA® should be used with caution in patients with known cardiovascular disease (e.g., heart failure, myocardial infarction or ischemia, conduction abnormalities), cerebrovascular disease, or conditions that predispose the patient to hypotension (e.g., dehydration, hypovolemia, and treatment with antihypertensive medications).

Seizures

As with other antipsychotic drugs, INVEGA® should be used cautiously in patients with a history of seizures or other conditions that potentially lower the seizure threshold.

Potential for Gastrointestinal Obstruction

Because the INVEGA® tablet is non-deformable and does not appreciably change shape in the gastrointestinal tract INVEGA® should not ordinarily be administered to patients with preexisting severe gastrointestinal narrowing (pathologic or iatrogenic) or in patients with dysphagia or significant difficulty in swallowing tablets. There have been rare reports of obstructive symptoms in patients with known strictures in association with the ingestion of drugs in non-deformable controlled-release formulations. Due to the controlled-release design of the dosage form, INVEGA® should only be used in patients who are able to swallow the tablet whole. (See Section *Dosage and Administration*)

Elderly Patients with Dementia

INVEGA® has not been studied in elderly patients with dementia.

Overall Mortality

In a meta-analysis of 17 controlled clinical trials, elderly patients with dementia treated with other atypical antipsychotic drugs, including risperidone, aripiprazole, olanzapine, and quetiapine, had an increased risk of

mortality compared to placebo. Among those treated with risperidone, the mortality was 4% compared with 3.1% for placebo.

Cerebrovascular Adverse Events

In placebo-controlled trials in elderly patients with dementia treated with some atypical antipsychotic drugs, including risperidone, aripiprazole, and olanzapine, there was a higher incidence of cerebrovascular adverse events (cerebrovascular accidents and transient ischemic attacks) including fatalities, compared to placebo.

Leukopenia, Neutropenia, and Agranulocytosis

Events of leukopenia, neutropenia, and agranulocytosis have been reported with antipsychotic agents, including INVEGA®. Agranulocytosis has been reported very rarely (< 1/10000 patients) during postmarketing surveillance.

Patients with a history of a clinically significant low white blood cell count (WBC) or a drug-induced leukopenia/neutropenia should be monitored during the first few months of therapy and discontinuation of INVEGA® should be considered at the first sign of a clinically significant decline in WBC in the absence of other causative factors.

Patients with clinically significant neutropenia should be carefully monitored for fever or other symptoms or signs of infection and treated promptly if such symptoms or signs occur. Patients with severe neutropenia (absolute neutrophil count < 1 X 10⁹/L) should discontinue INVEGA® and have their WBC followed until recovery.

Venous Thromboembolism

Cases of venous thromboembolism (VTE) have been reported with antipsychotic drugs. Since patients treated with antipsychotics often present with acquired risk factors for VTE, all possible risk factors for VTE should be identified before and during treatment with INVEGA® and preventive measures undertaken.

Parkinson's Disease and Dementia with Lewy Bodies

Physicians should weigh the risks versus the benefits when prescribing antipsychotic drugs, including INVEGA®, to patients with Parkinson's Disease or Dementia with Lewy Bodies (DLB) since both groups may be at increased risk of Neuroleptic Malignant Syndrome as well as having an increased sensitivity to antipsychotic medications. Manifestation of this increased sensitivity can include confusion, obtundation, postural instability with frequent falls, in addition to extrapyramidal symptoms.

Priapism

Drugs with alpha-adrenergic blocking effects have been reported to induce priapism. Priapism has been reported with paliperidone during postmarketing surveillance (see Section *Adverse Reactions*). Patients should be informed to seek urgent medical care in case that priapism has not been resolved within 3-4 hours.

Body Temperature Regulation

Disruption of the body's ability to reduce core body temperature has been attributed to antipsychotic agents. Appropriate care is advised when prescribing INVEGA® to patients who will be experiencing conditions which may contribute to an elevation in core body temperature, e.g., exercising strenuously, exposure to extreme heat, receiving concomitant medication with anticholinergic activity, or being subject to dehydration.

Antiemetic Effect

An antiemetic effect was observed in preclinical studies with paliperidone. This effect, if it occurs in humans, may mask the signs and symptoms of overdosage with certain drugs or of conditions such as intestinal obstruction, Reye's syndrome, and brain tumor.

Intraoperative Floppy Iris Syndrome

Intraoperative floppy iris syndrome (IFIS) has been observed during cataract surgery in patients treated with medicines with alpha1a-adrenergic antagonist effect, such as INVEGA (see Section *Adverse Reactions*).

IFIS may increase the risk of eye complications during and after the operation. Current or past use of medicines with alpha1a-adrenergic antagonist effect should be made known to the ophthalmic surgeon in advance of surgery. The potential benefit of stopping alpha1 blocking therapy prior to cataract surgery has not been established and must be weighed against the risk of stopping the antipsychotic therapy.

Conditions with decreased gastro-intestinal transit time

Conditions leading to shorter gastrointestinal transit time, e.g., diseases associated with chronic severe diarrhea, may result in a reduced absorption of paliperidone.

Renal impairment

The plasma concentrations of paliperidone are increased in patients with renal impairment and, therefore, dosage adjustment may be required in some patients (see Section *Dosage and Administration*; and *Pharmacokinetic Properties*). No data are available in patients with a creatinine clearance below 10 ml/min. Paliperidone should not be used in patients with creatinine clearance below 10 ml/min.

Hepatic impairment

No data are available in patients with severe hepatic impairment (Child-Pugh class C). Caution is recommended if paliperidone is used in such patients.

INTERACTIONS

Caution is advised when prescribing INVEGA® with drugs known to prolong the QT interval e.g., class IA antiarrhythmics (e.g., quinidine, disopyramide) and class III antiarrhythmics (e.g., amiodarone, sotalol), some antihistaminics, some other antipsychotics and some antimalarials (e.g., mefloquine).

Potential for INVEGA to Affect Other Drugs

Paliperidone is not expected to cause clinically important pharmacokinetic interactions with drugs that are metabolized by cytochrome P-450 isozymes. *In vitro* studies in human liver microsomes showed that paliperidone does not substantially inhibit the metabolism of drugs metabolized by cytochrome P450 isozymes, including CYP1A2, CYP2A6, CYP2C8/9/10, CYP2D6, CYP2E1, CYP3A4, and CYP3A5. Therefore, paliperidone is not expected to inhibit clearance of drugs that are metabolized by these metabolic pathways in a clinically relevant manner. *In vitro* studies indicated that paliperidone is not an inducer of CYP1A2, 2C19, or 3A4 activity.

Co-administration of INVEGA® with divalproex sodium prolonged-release tablets increased the exposure to paliperidone.

Paliperidone is a weak inhibitor of P-glycoprotein (P-gp) at high concentrations. No *in vivo* data are available and the clinical relevance is unknown.

Given the primary CNS effects of paliperidone (see Section *Adverse Reactions*), INVEGA® should be used with caution in combination with other centrally acting drugs and alcohol. Paliperidone may antagonize the effect of levodopa and other dopamine agonists.

Because of its potential for inducing orthostatic hypotension (see Section *Warnings and Precautions: Orthostatic Hypotension*), an additive effect may be observed when INVEGA® is administered with other therapeutic agents that have this potential.

Pharmacokinetic interaction between INVEGA® and lithium is unlikely.

Co-administration of INVEGA® at steady-state (12 mg once daily) with divalproex sodium extended-release tablets (500 mg to 2000 mg once daily) did not affect the steady-state pharmacokinetics of valproate.

Potential for Other Drugs to Affect INVEGA®

Paliperidone is not a substrate of CYP1A2, CYP2A6, CYP2C9, CYP2C19, and CYP3A5. This suggests that an interaction with inhibitors or inducers of these isozymes is unlikely. While *in vitro* studies indicate that CYP2D6 and CYP3A4 may be minimally involved in paliperidone metabolism, there are no indications *in vitro* nor *in vivo* that these isozymes play a significant role in the metabolism of paliperidone. *In vitro* studies have shown that paliperidone is a P-gp substrate.

It takes 2-3 weeks for full induction to be achieved and upon discontinuation of the inducer the effect wears off over a similar time period. Other medicinal products or herbals which are inducers, e.g. rifampicin and St John's wort (*Hypericum perforatum*) may have similar effects on paliperidone.

Paliperidone is metabolized to a limited extent by CYP2D6 (see Section *Pharmacokinetics Properties: Metabolism and Elimination*). In an interaction study in healthy subjects in which INVEGA® was administered concomitantly with paroxetine, a potent CYP2D6 inhibitor, no clinically relevant effects on the pharmacokinetics of paliperidone were observed.

Co-administration of INVEGA® once daily with carbamazepine 200 mg twice daily caused a decrease of approximately 37% in the mean steady-state C_{max} and AUC of paliperidone. This decrease is caused, to a substantial degree, by a 35% increase in renal clearance of paliperidone likely as a result of induction of renal P-gp by carbamazepine. A minor decrease in the amount of drug excreted unchanged in the urine suggests that there was little effect on the CYP metabolism or bioavailability of paliperidone during carbamazepine co-administration. On initiation of carbamazepine, the dose of INVEGA® should be re-evaluated and increased if necessary. Conversely, on discontinuation of carbamazepine, the dose of INVEGA® should be re-evaluated and decreased if necessary.

Paliperidone, a cation under physiological pH, is primarily excreted unchanged by the kidneys, approximately half via filtration and half via active secretion. Concomitant administration of trimethoprim, a drug known to inhibit active renal cation drug transport, did not influence the pharmacokinetics of paliperidone.

Co-administration of a single dose of INVEGA® 12 mg with divalproex sodium extended-release tablets (two 500 mg tablets once daily) resulted in an increase of approximately 50% in the C_{max} and AUC of paliperidone. Dosage reduction for INVEGA® should be considered when INVEGA® is co-administered with valproate after clinical assessment.

Pharmacokinetic interaction between lithium and INVEGA® is unlikely.

Concomitant Use of INVEGA® with Risperidone

Concomitant Use of INVEGA® with risperidone has not been studied. Since paliperidone is an active metabolite of risperidone, consideration should be given to the additive paliperidone exposure if risperidone is coadministered with INVEGA®.

Concomitant use of INVEGA® with psychostimulants

The combined use of psychostimulants (e.g. methylphenidate) with paliperidone can lead to the emergence of extrapyramidal symptoms upon change of either or both treatments (see Section *Warnings and Precautions*).

Pregnancy and Breast-feeding

Pregnancy

The safety of paliperidone for use during human pregnancy has not been established.

A retrospective observational cohort study based on a US claims database compared the risk of congenital malformations for live births among women with and without antipsychotic use during the first trimester of pregnancy. Paliperidone, the active metabolite of risperidone, was not specifically evaluated in this study. The risk of congenital malformations with risperidone, after adjusting for confounder variables available in the database, was elevated compared to no antipsychotic exposure (relative risk=1.26, 95% CI: 1.02-1.56). No biological mechanism has been identified to explain these findings and teratogenic effects have not been observed in non-clinical studies. Laboratory animals treated with a high dose of paliperidone showed a slight

increase in fetal deaths. This high dose was toxic to the mothers. The offspring was not affected at exposures 20- to 34-fold the maximum human exposure.

Neonates exposed to antipsychotic drugs (including paliperidone) during the third trimester of pregnancy are at risk for extrapyramidal and/or withdrawal symptoms that may vary in severity following delivery. These symptoms in the neonates may include agitation, hypertonia, hypotonia, tremor, somnolence, respiratory distress, or feeding disorder.

INVEGA® should only be used during pregnancy if the benefits outweigh the risks. The effect of INVEGA® on labor and delivery in humans is unknown.

Use of antipsychotic drugs during the last trimester of pregnancy has been associated with reversible extrapyramidal symptoms in the neonate.

Breast-feeding

In animal studies with paliperidone and in human studies with risperidone, paliperidone was excreted in the milk. Therefore, women receiving INVEGA® should not breast-feed infants.

Effects on Ability to Drive and Use Machines

INVEGA® may interfere with activities requiring mental alertness and may have visual effects (see Section *Adverse Reactions*). Therefore, patients should be advised not to drive or operate machinery until their individual susceptibility is known.

ADVERSE REACTIONS

Clinical Trial Data

The safety of INVEGA® in the treatment of schizophrenia was evaluated in 1205 adult subjects with schizophrenia who participated in 3 double-blind, placebo-controlled 6-week trials, of whom 850 subjects received INVEGA® at fixed doses ranging from 3 mg to 12 mg once daily. The information in this section was derived from pooled data. The majority of ADRs were mild to moderate in severity.

The safety of INVEGA® in the treatment of acute manic and mixed episodes associated with bipolar I disorder was evaluated in a total of 3 clinical trials in adults (n = 1257). The conditions and duration of treatment with INVEGA® varied across these studies and included (in overlapping categories) placebo- and active-controlled, double-blind, and fixed- and flexible-dose studies. Of the 1257 adult subjects, 739 subjects received INVEGA® in the dose range of 3 mg to 12 mg once daily and 376 subjects received placebo.

The safety of INVEGA® was also evaluated in 622 subjects with schizoaffective disorder who participated in two double-blind, placebo-controlled, 6-week trials. In one of these trials, 206 subjects were assigned to one of two dose levels of INVEGA®: 6 mg with the option to reduce to 3 mg (n=108) or 12 mg with the option to reduce to 9 mg (n=98) once daily. In the other study, 214 subjects received flexible doses of INVEGA® (3-12 mg once daily). Both studies included subjects who received INVEGA® either as monotherapy or in combination with antidepressants and/or mood stabilizers.

The information in this section was derived from pooled data.

The majority of adverse reactions were mild to moderate in severity.

Double-Blind, Placebo-Controlled Data – Schizophrenia - adults

Adverse reactions reported by ≥ 2% of INVEGA®-treated subjects in the three 6-week double-blind, placebo-controlled, fixed-dose schizophrenia trials in adults are shown in Table 1.

*Among the 420 subjects treated with INVEGA®, 230 (55%) received INVEGA® as monotherapy and 190 (45%) received INVEGA® in combination with antidepressants and/or mood stabilizers

Monotherapy versus Combination Therapy

The designs of the two placebo-controlled, 6-week, double-blind trials in adults subjects with schizoaffective disorder included the option for subjects to receive antidepressants (except monoamine oxidase inhibitors) and/or mood stabilizers (lithium, valproate, or lamotrigine). In the subject population evaluated for safety, 230 (55%) subjects received INVEGA® as monotherapy and 190 (45%) subjects received INVEGA® in combination with antidepressants and/or mood stabilizers. When comparing these 2 subpopulations, only nausea occurred at a greater frequency ($\geq 3\%$ difference) in subjects receiving INVEGA® as monotherapy.

Dose-Related Adverse Reactions

In the placebo-controlled, 6-week high- and low-dose study in subjects with schizoaffective disorder, dystonia, dysarthria, and nasopharyngitis occurred more frequently (i.e., a difference of at least 3%) in subjects who received higher doses of INVEGA® compared with subjects who received lower doses. Hypertonia occurred more frequently in subjects who received lower doses of INVEGA® compared with subjects who received higher doses.

Other Clinical Trial Data

Paliperidone is the active metabolite of risperidone, therefore the adverse reaction profiles of these compounds (including both the oral and injectable formulations) are relevant to one another. This subsection includes additional adverse reactions reported with paliperidone and/or risperidone in clinical trials.

Adverse reactions reported by $\geq 2\%$ of INVEGA®-treated subjects with schizophrenia in a fixed-dose, placebo-controlled study are: hypersomnia, muscle contractions involuntary, tongue paralysis, insomnia, anxiety, epistaxis, muscle contracture, breast swelling.

Adverse reactions reported with paliperidone and/or risperidone by $\geq 2\%$ of INVEGA®-treated subjects in a pooled dataset of the 9 double-blind, placebo-controlled schizophrenia, bipolar disorder, and schizoaffective disorder trials are shown in Table 4.

Table 4. Adverse Drug Reactions Reported by $\geq 2\%$ of INVEGA®-Treated Subjects in a Pooled Dataset of the 9 Double-Blind, Placebo-Controlled Schizophrenia, Bipolar Disorder Trials. The Terms within each System Organ Class are Sorted Alphabetically.

System/Organ Class
Adverse Reaction
Infections and Infestations
Upper respiratory tract infection
Psychiatric Disorders
Insomnia

Nervous System Disorders
Akathisia*, Dystonia*, Parkinsonism*
Gastrointestinal Disorders
Abdominal discomfort, Diarrhea
Musculoskeletal and Connective Tissue Disorders
Musculoskeletal pain

* **Insomnia includes:** initial insomnia, middle insomnia; **Akathisia includes:** hyperkinesia, restless legs syndrome, restlessness; **Dystonia includes:** blepharospasm, cervical spasm, emprosthotonus, facial spasm, hypertonia, laryngospasm, muscle contractions involuntary, myotonia, oculogyration, opisthotonus, oropharyngeal spasm, pleurothotonus, risus sardonicus, tetany, tongue paralysis, tongue spasm, torticollis, trismus; **Parkinsonism includes:** akinesia, bradykinesia, cogwheel rigidity, drooling, extrapyramidal symptoms, glabellar reflex abnormal, muscle rigidity, muscle tightness, musculoskeletal stiffness.

Adverse reactions with paliperidone and/or risperidone by < 2% of INVEGA®-treated subjects in a pooled dataset of the 9 double-blind, placebo-controlled schizophrenia, bipolar disorder, and schizoaffective disorder trials are shown in Table 5.

Table 5. Adverse Reactions Reported with Paliperidone and/or Risperidone by < 2% of INVEGA®-Treated Subjects in a Pooled Dataset of the 9 Double-Blind, Placebo-Controlled Schizophrenia, Bipolar Disorder, and Schizoaffective Disorder Trials. The Terms within each System Organ Class are Sorted Alphabetically

System/Organ Class

Body temperature increased, Chest discomfort, Chills, Face edema, Gait abnormal, Edema*, Pyrexia, Thirst
Injury, Poisoning and Procedural Complications
Fall

* **Convulsion includes:** grand mal convulsion; **Dyskinesia includes:** athetosis, chorea, choreoathetosis, movement disorder, muscle twitching, myoclonus; **Menstrual disorder includes:** menstrual irregular, oligomenorrhoea; **Edema includes:** generalized edema, edema peripheral, pitting edema

Adverse reactions reported with paliperidone and/or risperidone in other clinical trials but not reported by INVEGA® (3-12mg)-treated subjects in a pooled dataset of the 9 double-blind, placebo-controlled schizophrenia, bipolar disorder, and schizoaffective disorder trials are shown in Table 6.

Table 6. Adverse Reactions Reported with Paliperidone and/or Risperidone in Other Clinical Trials but not Reported by INVEGA® (3-12 mg)-Treated Subjects in a Pooled Dataset of the 9 Double-Blind, Placebo-Controlled Schizophrenia, Bipolar Disorder, and Schizoaffective Disorder Trials. The Terms within each System Organ Class are Sorted Alphabetically

System/Organ Class
Adverse Reaction
Infections and Infestations
Eye infection
Blood and Lymphatic System Disorders
Eosinophil count increased
Endocrine Disorders
Glucose urine present
Metabolism and Nutritional Disorders
Hyperinsulinemia, Polydipsia
Psychiatric Disorders
Blunted affect, Confusional state
Nervous System Disorders
Balance disorder, Cerebrovascular disorder, Coordination abnormal, Depressed level of consciousness, Diabetic coma, Head titubation, Neuroleptic malignant syndrome, Unresponsive to stimuli
Eye Disorders
Eye movement disorder, Eye rolling, Glaucoma, Ocular hyperemia

Cardiac Disorders
Postural orthostatic tachycardia syndrome
Respiratory, Thoracic and Mediastinal Disorders
Dysphonia, Pneumonia aspiration, Pulmonary congestion, Rales, Respiratory tract congestion
Gastrointestinal Disorders
Fecaloma
Skin and Subcutaneous Tissue Disorder
Drug eruption, Hyperkeratosis, Urticaria
Musculoskeletal and Connective Tissue Disorders
Posture abnormal, Rhabdomyolysis
Reproductive System and Breast Disorders
Breast enlargement, Menstruation delayed
General Disorders
Body temperature decreased, Drug withdrawal syndrome, Induration, Malaise

Elderly

The safety of INVEGA® was evaluated in 81 elderly subjects with schizophrenia (65 years of age and older) who received either flexible doses (n = 76) or fixed doses (n = 5) of INVEGA® in a range of 3 to 12 mg once daily for a duration of up to 6 weeks during double-blind, placebo-controlled trials. Although this dataset does not allow for a systematic direct comparison between elderly and non-elderly subjects, the safety profile was similar in the two populations. However, based on these limited data and consistent with general clinical practice, a greater sensitivity of older individuals to adverse reactions cannot be ruled out.

Events of Particular Interest to the Class

Extrapyramidal Symptoms (EPS). Pooled data from the three 6-week double-blind, placebo-controlled, fixed-dose schizophrenia studies (see Section *Pharmacodynamic Properties: Clinical Efficacy*) showed no differences in treatment-emergent EPS between placebo (11%) and INVEGA® 3 and 6 mg doses (13% and 10%, respectively). Dose-relatedness for EPS was seen with the two higher doses of INVEGA® (25% and 26% for the 9 and 12 mg doses, respectively). EPS included a pooled analysis of the following terms: dyskinesia, dystonia, hyperkinesia, Parkinsonism, and tremor. Pooled data from the two 6-week, double-blind, placebo-controlled studies in subjects with schizoaffective disorder (see Section *Pharmacodynamic Properties: Clinical Efficacy*) showed similar results.

Weight Gain. In the pooled data from the three placebo-controlled, 6-week, fixed-dose adult schizophrenia studies (see Section *Pharmacodynamic Properties: Clinical Efficacy*), the proportions of subjects meeting a weight gain criterion of $\geq 7\%$ of body weight were compared, revealing a similar incidence of weight gain for INVEGA® 3 mg and 6 mg (7% and 6%, respectively) compared with placebo (5%), and a higher incidence of weight gain for INVEGA® 9 mg and 12 mg (9% and 9%, respectively).

Weight gain was assessed in a 6-week, double-blind, placebo-controlled study and an open-label extension with a median duration of exposure to INVEGA® of 182 days. In the double-blind, placebo-controlled study, a higher percentage of INVEGA® low dose (6%), medium dose (13%), and high dose (13%) treated subjects [see Section *Pharmacodynamic properties*] had an increase in body weight of $\geq 7\%$ from baseline compared with placebo-treated subjects (2%). In the open-label long-term study the proportion of total subjects treated with INVEGA® with an increase in body weight of $\geq 7\%$ from baseline was 33%. When treating with INVEGA®, weight gain should be assessed against that expected with normal growth. When taking into consideration the median duration of exposure to INVEGA® in the open-label study (182 days) along with expected normal growth in this population, an assessment of standardized scores relative to normative data provides a more clinically relevant measure of changes in weight. The mean change from open-label baseline to endpoint in standardized score for weight was 0.1 (4% above the median of normative data). Based on comparison to the normative data, these changes are not considered to be clinically significant.

In the pooled data from the two placebo-controlled, 6-week studies in subjects with schizoaffective disorder (see Section *Pharmacodynamic Properties: Clinical Efficacy*), a higher percentage of INVEGA® treated subjects

(5%) had an increase in body weight of $\geq 7\%$ compared with placebo-treated subjects (1%). In the study that examined high- and low-dose groups, the increase in body weight of $\geq 7\%$ was 3 % in the low-dose group, 7% in high-dose group, and 1% in the placebo group.

Laboratory Tests: Serum Prolactin. Based on pooled data from the three 6-week double-blind, placebo-controlled, fixed-dose schizophrenia studies (see Section *Pharmacodynamic Properties: Clinical Efficacy*), increases in serum prolactin were observed in subjects of both genders who received INVEGA®. Maximum mean increases of serum prolactin concentrations were generally observed on Day 15 of treatment, but remained above baseline levels at study endpoint.

Clinical Trials: Adverse reactions in a Long-Term, Placebo-Controlled Study

The safety of INVEGA® was also evaluated in a long-term trial designed to assess the maintenance of effect with INVEGA® in adults with schizophrenia (see Section *Pharmacodynamic Properties: Clinical Efficacy*). In general, the types, frequencies, and severities of adverse reactions reported during the initial 14-week open-label phase of this study were comparable to those reported in the 6-week, placebo-controlled, fixed-dose studies. The Adverse reactions reported during the long-term double-blind phase of this study were similar in type and severity to those observed in the initial 14-week open-label phase, but occurred at generally lower frequencies.

Postmarketing Data

In addition to the adverse reactions reported during clinical trials and listed above, the following adverse reactions have been reported during postmarketing experience with paliperidone and/or risperidone (Tables 7). In each table, the frequencies are provided according to the following convention:

Very common	$\geq 1/10$
Common	$\geq 1/100$ to $<1/10$
Uncommon	$\geq 1/1,000$ to $<1/100$
Rare	$\geq 1/10,000$ to $<1/1,000$
Very rare	$<1/10,000$, including isolated reports
Not known	Cannot be estimated from the available data

In Table 7 Adverse reactions are presented by frequency category based on spontaneous reporting rate.

Table 7. Adverse Reactions Identified During Postmarketing Experience with paliperidone and/or risperidone by Frequency Category Estimated from Spontaneous Reporting Rates with Paliperidone	
Blood and Lymphatic System Disorders	
Very rare	Agranulocytosis, Thrombocytopenia
Endocrine Disorders	
Not known	Inappropriate antidiuretic hormone secretion
Metabolism and Nutrition Disorders	
Very rare	Diabetes mellitus, Diabetic ketoacidosis, Hypoglycaemia
Not known	Water intoxication
Psychiatric Disorders	
Very rare	Catatonia, Mania, Somnambulism
Not known	Sleep-related eating disorder
Nervous System Disorders	
Very rare	Dysgeusia
Eye Disorders	
Not known	Floppy iris syndrome (intraoperative)
Cardiac Disorders	
Very rare	Atrial fibrillation
Vascular Disorder	
Very rare	Deep vein thrombosis, Pulmonary embolism

Respiratory, Thoracic and Mediastinal Disorders	
<i>Very rare</i>	Sleep apnea syndrome
Gastrointestinal Disorders	
<i>Very rare</i>	Pancreatitis
<i>Very rare</i>	Ileus
Hepatobiliary Disorders	
<i>Not known</i>	Jaundice
Skin and Subcutaneous Tissue Disorders	
<i>Rare</i>	Angioedema
<i>Very rare</i>	Alopecia
<i>Not known</i>	Stevens-Johnson syndrome/Toxic epidermal necrolysis
Renal and Urinary Disorders	
<i>Very rare</i>	Urinary retention
Pregnancy, Puerperium and Perinatal Conditions	
<i>Very rare</i>	Drug withdrawal syndrome neonatal
Reproductive System and Breast Disorders	
<i>Very rare</i>	Priapism
General Disorders	
<i>Very rare</i>	Hypothermia

Safety Information Reported with Risperidone

Paliperidone is an active metabolite of risperidone. The release profile and pharmacokinetic characteristics of INVEGA® are considerably different than those observed with oral immediate-release risperidone formulations (see Section *Pharmacokinetic Properties*). Safety information reported with risperidone in clinical trials and postmarketing experience can be found in local labeling for risperidone.

Overdose

Signs and symptoms

In general, expected signs and symptoms are those resulting from an exaggeration of paliperidone's known pharmacological effects, i.e., drowsiness and sedation, tachycardia and hypotension, QT prolongation, and extrapyramidal symptoms. Torsade de pointes and ventricular fibrillation have been reported in the setting of overdose with oral paliperidone. In the case of acute overdosage, the possibility of multiple drug involvement should be considered.

Treatment

Consideration should be given to the extended-release nature of the product when assessing treatment needs and recovery. There is no specific antidote to paliperidone. General supportive measures should be employed. Establish and maintain a clear airway and ensure adequate oxygenation and ventilation. Cardiovascular monitoring should commence immediately and should include continuous electrocardiographic monitoring for possible arrhythmias. Hypotension and circulatory collapse should be treated with appropriate measures such as intravenous fluid and/or sympathomimetic agents. Administration of activated charcoal together with a laxative should be considered. In case of severe extrapyramidal symptoms, anticholinergic agents should be administered. Close supervision and monitoring should continue until the patient recovers.

LIST OF EXCIPIENTS

Polyethylene oxide, sodium chloride, povidone, stearic acid, butylated hydroxytoluene, ferric oxide (yellow), ferric oxide (red), iron oxide black, hydroxyethyl cellulose, polyethylene glycol, cellulose acetate, acetone, purified water, color overcoating material white, carnauba wax, ink water-based black.

PHARMACEUTICAL PARTICULARS

Shelf life

2 years at room temperature

Special Precautions for Storage

Do not store above 30°C. Protect from moisture.

Keep out of sight and reach of children.
